Emissions Inventory

Change	Effect
<u>Emissions Inventory Calculation</u> In EDMS 3.2 and 3.21 when the same aircraft-engine combination was used more than once in a study, by assigning a unique identification to the combination, the emissions inventory reported erroneous values for the GSE and APU values. The GSE and APU total emissions displayed for each individual combination was actually the sum of the respective GSE or APU emissions for all occurrences of that combination. In version 3.22 this error has been corrected.	The emissions inventory results reported in EDMS 3.22 correctly distinguish between each individual aircraft-engine combination in the study. This bug did not have any effect on concentration results.
